THE PATCH FRAME AND ITS RELATIONS WITH SEPARATION IN POINT-FREE TOPOLOGY

ABSTRACT.

1. Introduction

Aquí va la introducción.

2. Preliminaries

3. Hausdorff Properties implies patch triviality

Gadgets:

A the base frame

Its point space S = pt(A).

The compact saturated sets of S,

 $\mathcal{Q}(S)$.

The preframe of open filters of A,

 A^{\wedge} .

The preframe of open filters of $\Omega(S)$.

$$\Omega(S)^{\wedge}$$
.

First we recall that every open filter $F \in A^{\wedge}$ has three faces, that is, determines (and its determine) by :

- The compact saturated $Q \in \mathcal{Q}S$.
- $\nabla \in \Omega(S)^{\wedge}$.
- The compact quotient $A \to A_F$.
- The fitted nucleus v_F .

Hoffman-Mislove can be rephrase:

There is a bijection between compact quotients of A and compact saturated sets of S

Definition 3.1. A frame has KC if every compact quotient of A is a closed one. In other words every compact sublocale is close.

Denote by $\Re rm$ the subcategory of Frm of Hausdorff frames in the sense of Johnstone and Shu.

The block structure on a frame is an important problem and its related with some separation properties of frames.

1

Proposition 3.2. For every $A \in \mathcal{H}rm$ the interval corresponding to the block determined by a open filter $F \in A^{\wedge}$ is trivial, that is,

$$[v_F, w_F] = \{*\}$$

Proof. We know that for all $F \in A^{\wedge}$ the following holds: $v_F \leq w_F$. As a contradition, suppose that exists $F \in A^{\wedge}$ such that $w_F \nleq v_F$, that is, exists $a \in A$ such that $w_F(a) \nleq v_F(a)$.

Note that $w_F(a) \neq 1$, otherwise

$$1 = w_F(a) = \bigwedge \{ p \in M \mid a \le p \} \le p$$

and this is a contradition because $p \neq 1$.

Then $1 \neq w_F(a) \nleq v_F(a)$ and for the property (H), exists $u \in A$ such that

(1)
$$u \nleq w_F(a) \quad \mathbf{y} \quad \neg u \nleq v_F(a)$$

Note that $0 \le a$, then $w_F(0) \le w_F(a)$ and $v_F(0) \le v_F(a)$. Thus, for 1 we have that

(2)
$$i) u \nleq w_F(0) \quad \text{y} \quad ii) \neg u \nleq v_F(0).$$

For 2-(i) is true that $u \nleq \bigwedge M$, in particular, $u \nleq p$ for all $p \in M$. Therefore, $\neg u \leq p$ and $\neg u \leq w_F(0)$. If 2-(ii) is true, then $u \notin F$, in otherwise

$$u \in F \Rightarrow v_u \le f \Rightarrow v_u(0) = \neg u \le f(0)$$

and this is a contradition. Thus, for the Birkhoff's separation lemma, exists a completely prime filter G such that $u \notin G \supseteq F$. We take

$$q = \bigvee \{y \in A \mid y \notin G\}$$

the point corresponding to G. Thus, $u \notin G$, $u \le q$. If $q \notin F$, then exists $m \in M$ such that $q \le m$. Sinse q is maximum, q = m or m = 1, but $m \ne 1$ ($1 \in F$ and $M = A \setminus F$), then $m = q \in M$. Hence $u \nleq q$ and this is a contradition. Therefore $v_F = w_F$.

Proposition 3.3. Every Hausdorff frame A (in the sense of Johnstone and Shou) is tidy, that is, A is patch trivial.

Proof.
